Code Explanation

Following the needs for fulfilling all four of the learning outcomes, I had applied all of them for this project. Firstly, this project successfully scaffolds the entire project using the Vue 3 application while also connecting it to the external REST API that is built in index.js file. Next, this project also implements Axios HTTP client to handle interceptors for logging and error handling by centralizing API calls in the employeeApi.js file. Then, this project also includes forms to capture user inputs such as employee ID and name using v-model which also include data validation with specific rules in the EmployeeForm.vue. Finally, to handle full CRUD operations against a MySQL database, this project implements an Express API.

Challenges

There are many challenges I stumbled upon while completing this assignment. One of them is the initial confusion when handling attributes of the employee object where I got confused with the id of employee object in the database and the Employee ID which are two different things. To resolve this issue, I made two different attributes that differentiated both of the data. Other than that, there are many typos that I made while completing this project including misplacing a capital letter and additions of new letters. This led to multiple errors when I tested the system after frontend implementation which then can be resolved by inspecting web dev tools for errors.
